Description:

The CU Function Finder is a website that's designed to better allow CU students to connect with each other by streamlining the creation and attendance of different events. Students can host and advertise these events to a larger audience or they can create private events, which are only shown to and available to their friends. It should be noted that before you have RSVP'd to an event the exact event address is obscured. In addition to event hosting we have a rating system that allows both hosts and guests of these events to retroactively rate each other. We wanted to create a system that would allow the end-user to "filter" the people who are wanting to attend their events without requiring much direct moderation or limiting specific users. This rating system enables a host to know if a student has been problematic at past events and also gives guests the opportunity to know which events are likely going to flop or soar. Our website also has a notifications system which enables hosts to see when someone has requested to RSVP to their private event, and enables guests to see if their RSVP request was accepted.

Contributions:

Sawyer:

I created the SQL database, helped with git errors, created the user testing plan, did user testing, helped plan new features, met with the TA for the team, did the lab assignments, and created the presentation. I also acted as the point of contact between team members. Plus I helped track and plan new features.

Dawson:

I worked on front end development for the web app. My contributions ranged from building a prototype in Figma, to creating the handlebars pages. Specifically I made the home, user, event, event_edit pages. The work for these pages also entailed creating JavaScript functions like the tag-filtering on the home page, and personalizing the feed of a logged in user. I also learned Multer to provide photo support, for both user profiles and events. I also handled the deployment of our app on Render.

Ryan:

I created the backend API calls for the Register, Login, Logout, Home, Event and Event Creation, Account/User, Reviews, Notifications, and Search Pages. I also created the Login page, Register page, and the Search page for our web app. Besides this, I did various testing and bug fixes for the API calls I'd created and their associated pages. I also created the README.md file for the project repo.

Ayub:

I handled the user test cases and built out the Stripe architecture, even though we couldn't get it fully shipped in time. I also helped with several backend API calls and spent a lot of time on bug fixes, especially getting the Docker environment stable and resolving merge conflicts when we integrated everyone's code. I made sure the core registration logic and payment infrastructure were solid so the team could move forward.

Abrham:
I was responsible for the frontend design system and the notifications page. I built the project-wide stylesheet, header, and footer based on the Figma wireframes. I created the notifications page with a Handlebars template and integrated it with the backend. I implemented all four notification acceptance criteria. I also built the category filter tabs and the Mark All Read feature. I also contributed to the notifications route and session handling in index.js and custom Handlebars helpers for timestamp formatting. Technologies used: Node.js, Express, PostgreSQL, Handlebars, Bootstrap 5, CSS, and Docker.

Test Results:

Test 1:

Test one was testing the login/sign up aspect of our site.
In this test I asked a tester to create an account and then login to that account. I noticed that the user immediately looked at the top bar instead of looking for the login buttons on the main page. This was because it was what they had experienced on other websites. Their behavior was consistent with the use case as they were able to successfully navigate to the register page and make an account. The one thing that I noticed was that while creating an account the user started creating a password that didn't meet the requirements as the requirements don't show up until you start typing a password.

Test 2:

Test two was testing the search function
When asked to search for a specific event the users first instinct was to scroll down the homepage and manually look through the events on the homepage. This went against what we expected. This was because the user thought that it would be faster to find the event they wanted. As we planned for the users to use the search function. The user did find their event, however, this leads me to believe that we need to increase the size of the search button or make another way to get to the search page placed somewhere more obvious.

Test 3:

Test Three was testing the create event function
When the user was asked to create an event they found the event creation page with no issues. They then filled out the necessary information with no trouble. They performed completely within what was expected for and planned out in the user flow. They did try to create an event for the year 8 which they were not allowed to do. I believe that the reason for this was because they didn't have an actual event they were making so they created whatever they wanted.

Test 4:

Test four was testing the edit event function.
The user had some difficulty locating the edit event function from the home page as they had to search up their own event to edit its details. I also found that the user was confused because there were different fields for the edit event than there were for the event creation page. This led to a large delay in editing their event. I would recommend that the two forms are unified so that they are the same and that users are not confused by the differing fields.
